Basic PostgreSQL Commands

Understanding the fundamental PostgreSQL commands is the first step toward effective database interaction. These commands facilitate connecting to the PostgreSQL server, switching databases, and obtaining essential information about the current environment.

Connecting to PostgreSQL

The primary command-line tool to access PostgreSQL is *psql*. It allows users to connect to a PostgreSQL database server, execute queries, and manage databases interactively.

- `psql -U username -d dbname`: Connect to a specific database using a username.
- `psql -h hostname -U username -d dbname`: Connect specifying the host, user, and database.
- `\q`: Quit the psql interface.

Getting Server and Database Information

These commands provide details about the PostgreSQL environment, including version information and current connection status.

- `SELECT version();` – Displays the PostgreSQL server version.
- `\conninfo` – Shows information about the current database connection.
- `\l` or `\list` – Lists all databases available on the server.

Database and Table Management

Managing databases and tables is a core aspect of PostgreSQL administration. This section covers commands for creating, altering, and deleting databases and tables.

Creating and Dropping Databases

Database creation and removal are fundamental operations when organizing data storage within PostgreSQL.

- **CREATE DATABASE dbname;** – Creates a new database.
- **DROP DATABASE dbname;** – Deletes an existing database permanently.
- **\c dbname** – Connects to a specified database.

Table Operations

Tables are the primary structures for storing data. PostgreSQL provides commands for creating, modifying, and deleting tables.

- **CREATE TABLE tablename (column_name data_type [constraints], ...);** – Creates a new table with defined columns.
- **ALTER TABLE tablename ADD COLUMN column_name data_type;** – Adds a new column to an existing table.
- **ALTER TABLE tablename DROP COLUMN column_name;** – Removes a column from a table.

- **DROP TABLE tablename;** – Deletes a table and its data.
- **\d tablename** – Describes the structure of a table.

Data Querying and Manipulation

PostgreSQL commands for querying and modifying data are essential for database operations. This section highlights commands to retrieve, insert, update, and delete data efficiently.

Retrieving Data

The **SELECT** statement is the cornerstone of data retrieval in PostgreSQL, enabling complex queries and data analysis.

- **SELECT * FROM tablename;** – Retrieves all rows and columns from a table.
- **SELECT column1, column2 FROM tablename WHERE condition;** – Retrieves specific columns with filtering conditions.
- **SELECT COUNT(*) FROM tablename;** – Counts the number of rows in a table.

Inserting, Updating, and Deleting Data

Data manipulation commands allow insertion of new records, modification of existing data, and removal of unwanted data.

- **INSERT INTO tablename (column1, column2) VALUES (value1, value2);** – Inserts a new row.

- **UPDATE tablename SET column1 = value1 WHERE condition;** – Updates existing rows based on a condition.
- **DELETE FROM tablename WHERE condition;** – Deletes rows matching the condition.

User and Permission Management

Managing users and their privileges is crucial for securing PostgreSQL databases. This section outlines commands for creating roles, granting permissions, and managing access control.

Creating and Managing Roles

Roles in PostgreSQL represent users or groups. Administrators can create roles with specific attributes and privileges.

- **CREATE ROLE rolename WITH LOGIN PASSWORD 'password';** – Creates a new role with login capability.
- **ALTER ROLE rolename WITH SUPERUSER;** – Grants superuser privileges to a role.
- **DROP ROLE rolename;** – Deletes a role from the server.

Granting and Revoking Permissions

Controlling access to database objects is managed through GRANT and REVOKE commands, ensuring data security and proper user rights management.

- **GRANT SELECT, INSERT ON tablename TO rolename;** – Grants specified privileges on a table to a role.
- **REVOKE INSERT ON tablename FROM rolename;** – Removes specific privileges from a role.
- **GRANT ALL PRIVILEGES ON DATABASE dbname TO rolename;** – Grants all permissions on a database.

Backup, Restore, and Maintenance

Maintaining database integrity and availability requires regular backup and restore operations alongside routine maintenance commands. This section covers essential tools and commands for these tasks.

Backing Up and Restoring Databases

PostgreSQL offers versatile utilities for backing up data and restoring it when necessary, critical for disaster recovery and data migration.

- **pg_dump dbname > backupfile.sql** – Creates a logical backup of a database.
- **pg_restore -d dbname backupfile.dump** – Restores a database from a custom-format dump.
- **psql dbname < backupfile.sql** – Restores a database from a plain SQL script.

Vacuuming and Analyzing

Routine maintenance commands like `vacuum` and `analyze` help optimize database performance by cleaning up dead tuples and updating statistics.

- **VACUUM;** – Reclaims storage occupied by dead tuples.
- **VACUUM FULL;** – Performs a more comprehensive cleanup, locking tables during the process.
- **ANALYZE;** – Updates statistics used by the query planner.
- **VACUUM ANALYZE;** – Combines vacuuming and analyzing in one command.

Performance and Optimization Commands

Optimizing PostgreSQL performance involves using specific commands to monitor, tune, and analyze database activity and query efficiency. This section highlights key commands for performance management.

Monitoring Database Activity

PostgreSQL provides commands to monitor current queries, connections, and locks to diagnose potential bottlenecks.

- **SELECT * FROM pg_stat_activity;** – Displays active queries and sessions.
- **SELECT * FROM pg_locks;** – Shows current locks held in the database.
- **SELECT * FROM pg_stat_database;** – Provides database-wide statistics.

Query Planning and Execution

Analyzing query plans helps optimize SQL statements for better performance by understanding how PostgreSQL executes them.

- **EXPLAIN SELECT * FROM tablename;** – Shows the query execution plan.
- **EXPLAIN ANALYZE SELECT * FROM tablename;** – Executes the query and shows the actual run time and plan.
