Basic Mathematical Terms

Understanding basic mathematical vocabulary is the first step in mastering pre algebra terms and definitions. These fundamental terms form the language of mathematics and are used consistently throughout various topics.

Term

A term is a single number, variable, or the product of numbers and variables separated by plus or minus signs in an expression. For example, in the expression $3x + 5$, both $3x$ and 5 are terms.

Expression

An expression is a combination of terms connected by addition, subtraction,

multiplication, or division, but it does not include an equal sign. Expressions can be simplified but not solved.

Equation

An equation is a mathematical statement that asserts the equality of two expressions, represented by the equal sign ($=$). Equations can be solved to find the value of unknown variables.

Coefficient

A coefficient is a numerical factor that multiplies a variable in a term. For example, in $7y$, the number 7 is the coefficient of the variable y .

Constant

A constant is a fixed value that does not change. In expressions or equations, constants are numbers without variables, such as 4 or -9.

Numbers and Their Types

Pre algebra terms and definitions include a range of number types that students must distinguish to apply mathematical concepts appropriately.

Whole Numbers

Whole numbers are non-negative integers starting from zero, including 0, 1, 2, 3, and so on. They do not include fractions or decimals.

Integers

Integers extend whole numbers to include negative numbers, zero, and positive numbers (... , -3, -2, -1, 0, 1, 2, 3, ...). They are important in operations involving positive and negative values.

Rational Numbers

Rational numbers are numbers that can be expressed as a ratio of two integers, where the denominator is not zero. This set includes fractions and terminating or repeating decimals.

Irrational Numbers

Irrational numbers cannot be expressed as a simple fraction. Their decimal expansions are non-terminating and non-repeating, such as π (pi) and the square root of 2.

Prime Numbers

Prime numbers are natural numbers greater than 1 that have no positive divisors other than 1 and themselves. Examples include 2, 3, 5, 7, and 11.

Composite Numbers

Composite numbers are natural numbers greater than 1 that have more than two positive divisors. For example, 4, 6, 8, 9, and 12 are composite numbers.

Operations and Expressions

The understanding of operations and how to manipulate expressions is central to pre algebra terms and definitions. These concepts prepare students for solving equations and working with algebraic expressions.

Addition and Subtraction

Addition and subtraction are fundamental arithmetic operations used to combine or remove quantities. They also apply to variables and expressions.

Multiplication and Division

Multiplication is repeated addition, and division is splitting a quantity into equal parts. Mastery of these operations is necessary for simplifying expressions and solving equations.

Order of Operations

The order of operations is a set of rules that determine the sequence in which operations should be performed to correctly evaluate expressions. The acronym PEMDAS helps remember the order: Parentheses, Exponents, Multiplication and Division (left to right), Addition and Subtraction (left to right).

Like Terms

Like terms are terms that have the same variable raised to the same power. Combining like terms simplifies expressions. For example, $5x$ and $3x$ are like terms, but $5x$ and $3y$ are not.

Distributive Property

The distributive property involves multiplying a single term by each term within parentheses. It is expressed as $a(b + c) = ab + ac$. This property is essential for expanding expressions.

Properties of Numbers

Pre algebra terms and definitions also focus on the properties of numbers, which dictate how operations behave and interact in expressions and equations.

Commutative Property

The commutative property states that the order of numbers does not affect the result of addition or multiplication. For example, $a + b = b + a$ and $ab = ba$.

Associative Property

The associative property indicates that the grouping of numbers does not change the sum or product. For instance, $(a + b) + c = a + (b + c)$ and $(ab)c = a(bc)$.

Identity Property

The identity property refers to the existence of an identity element that does not change a number when combined with it. For addition, the identity is 0 , and for multiplication, it is 1 .

Inverse Property

The inverse property involves numbers that, when combined with a given number, result in the identity element. The additive inverse of a number a is $-a$, and the multiplicative inverse of a nonzero number a is $1/a$.

Introduction to Variables and Equations

Variables and equations are key components of pre algebra terms and definitions. They introduce the concept of unknown values and the methods used to find them.

Variable

A variable is a symbol, usually a letter, that represents an unknown or changeable value. Variables allow expressions and equations to represent general mathematical relationships.

Expression

Expressions involving variables combine constants, coefficients, and variables using operations. For example, $4x + 7$ is an algebraic expression.

Equation

An equation sets two expressions equal to each other and often contains variables to be solved. Solving equations is a fundamental skill in pre algebra.

Solution

A solution is the value of the variable that makes the equation true. Finding solutions involves isolating the variable using inverse operations.

Inequalities

Inequalities are mathematical statements that compare two expressions using symbols such as $<$, $>$, $\leq$, or $\geq$. They are similar to equations but show a range of possible values.

Geometry Terms in Pre Algebra

While primarily focused on numbers and operations, pre algebra terms and definitions also introduce basic geometry concepts that relate to algebraic thinking.

Point

A point represents an exact location in space and has no size or dimension. It is usually labeled with a capital letter.

Line

A line is a straight one-dimensional figure extending infinitely in both directions, defined by at least two points.

Line Segment

A line segment is part of a line bounded by two endpoints. It has a definite length.

Angle

An angle is formed by two rays sharing a common endpoint called the vertex. Angles are measured in degrees.

Perimeter

The perimeter is the total distance around the boundary of a two-dimensional shape, calculated by adding the lengths of all sides.

Area

Area measures the amount of space inside a two-dimensional shape, usually expressed in square units.
